### Activity 5: Consolidating Playbook plays

#### 1. Objectives:

- 1.1 Use **when** command in playbook for different OS distributions
- 1.2 Apply refactoring techniques in cleaning up the playbook codes

#### 2. Discussion:

We are going to look at a way that we can differentiate a playbook by a host in terms of which distribution the host is running. It's very common in most Linux shops to run multiple distributions, for example, Ubuntu shop or Debian shop and you need a different distribution for a one off-case or perhaps you want to run plays only on certain distributions.

It is a best practice in ansible when you are working in a collaborative environment to use the command git pull. git pull is a Git command used to update the local version of a repository from a remote. By default, git pull does two things. Updates the current local working branch (currently checked out branch) and updates the remote-tracking branches for all other branches. git pull essentially pulls down any changes that may have happened since the last time you worked on the repository.

#### Requirement:

In this activity, you will need to create a CentOS VM. Likewise, you need to activate the second adapter to a host-only adapter after the installations. Take note of the IP address of the CentOS VM. Make sure to use the command **ssh-copy-id** to copy the public key to CentOS. Verify if you can successfully SSH to CentOS VM.

#### Task 1: Use when command for different distributions

1. In the local machine, make sure you are in the local repository directory (**CPE232\_yourname**). Issue the command git pull. When prompted, enter the correct passphrase or password. Describe what happened when you issue this command. Did something happen? Why?

```
rustom@LocalMachine:~/CPE232_Rustom$ git pull
Already up to date.
```

- Git pulling

2. Edit the inventory file and add the IP address of the Centos VM. Issue the command we used to execute the playbook (the one we used in the last activity): `ansible-playbook --ask-become-pass install_apache.yml`. After executing this command, you may notice that it did not become successful in the Centos VM. You can see that the Centos VM has failed=1. Only the two remote servers have been changed. The reason is that Centos VM does not support "apt" as the package manager. The default package manager for Centos is "yum."

```

```

- The centos was failed but the 2 server changed

3. Edit the `install_apache.yml` file and insert the lines shown below.

```
---
- hosts: all
  become: true
  tasks:

    - name: update repository index
      apt:
        update_cache: yes
        when: ansible_distribution == "Ubuntu"

    - name: install apache2 package
      apt:
        name: apache2
        when: ansible_distribution == "Ubuntu"

    - name: add PHP support for apache
      apt:
        name: libapache2-mod-php
        when: ansible_distribution == "Ubuntu"
```

Make sure to save the file and exit.

```
GNU nano 6.2                                install_apache.yml *
---
- hosts: all
  become: true
  tasks:
    - name: update repository index
      apt:
        update_cache: yes
        when: ansible_distribution == "Ubuntu"
    - name: install apache2 package
      apt:
        name: apache2
        when: ansible_distribution == "Ubuntu"
    - name: add PHP support for apache
      apt:
        name: libapache2-mod-php
        when: ansible_distribution == "Ubuntu"
```

Run *ansible-playbook --ask-become-pass install\_apache.yml* and describe the result.

```

rustom@localmachine:~/CPE232_RUSTOM$ ansible-playbook --ask-become-pass install_apache.yml
BECOME password:

               rescued=0    ignored=0

```

- there is no problem in executing the playbook

If you have a mix of Debian and Ubuntu servers, you can change the configuration of your playbook like this.

- name: update repository index  
apt:  
    update\_cache: yes  
    when: ansible\_distribution in ["Debian", "Ubuntu"]

*Note:* This will work also if you try. Notice the changes are highlighted.

4. Edit the *install\_apache.yml* file and insert the lines shown below.

```
---
- hosts: all
  become: true
  tasks:

    - name: update repository index
      apt:
        update_cache: yes

rescued=0    ignored=0

```

- The playbook is executed properly

5. To verify the installations, go to CentOS VM and type its IP address on the browser. Was it successful? The answer is no. It's because the httpd service or the Apache HTTP server in the CentOS is not yet active. Thus, you need to activate it first.

- unable to connect since the httpd service is not yet active.

5.1 To activate, go to the CentOS VM terminal and enter the following:

*systemctl status httpd*

The result of this command tells you that the service is inactive.

```
[rustom@centos ~]$ systemctl status httpd
● httpd.service - The Apache HTTP Server
   Loaded: loaded (/usr/lib/systemd/system/httpd.service; disabled; vendor preset: disabled)
   Active: inactive (dead)
     Docs: man:httpd(8)
          man:apachectl(8)
[rustom@centos ~]$
```

5.2 Issue the following command to start the service:

*sudo systemctl start httpd*

```
[rustom@centos ~]$ sudo systemctl start httpd
```

(When prompted, enter the sudo password)

*sudo firewall-cmd --add-port=80/tcp*

(The result should be a success)

```
[rustom@centos ~]$ sudo firewall-cmd --add-port=80/tcp  
success  
[rustom@centos ~]$ █
```

5.3 To verify the service is already running, go to CentOS VM and type its IP address on the browser. Was it successful? (Screenshot the browser)

- After activating the httpd service, the testing is successful

### Task 2: Refactoring playbook

This time, we want to make sure that our playbook is efficient and that the codes are easier to read. This will also makes run ansible more quickly if it has to execute fewer tasks to do the same thing.

1. Edit the playbook *install\_apache.yml*. Currently, we have three tasks targeting our Ubuntu machines and 3 tasks targeting our CentOS machine. Right now, we try to consolidate some tasks that are typically the same. For example, we can consolidate two plays that install packages. We can do that by creating a list of installation packages as shown below:

```

---
- hosts: all
  become: true
  tasks:

    - name: update repository index Ubuntu
      apt:
        update_cache: yes
        when: ansible_distribution == "Ubuntu"

    - name: install apache2 and php packages for Ubuntu
      apt:
        name:
          - apache2
          - libapache2-mod-php
        state: latest
        when: ansible_distribution == "Ubuntu"

    - name: update repository index for CentOS
      dnf:
        update_cache: yes
        when: ansible_distribution == "CentOS"

    - name: install apache and php packages for CentOS
      dnf:
        name:
          - httpd
          - php
        state: latest
        when: ansible_distribution == "CentOS"

```

Make sure to save the file and exit.

```
GNU nano 6.2                                install_apache.yml
--
- hosts: all
  become: true
  tasks:
    - name: update repository index for ubuntu
      apt:
        update_cache: yes
        when: ansible_distribution == "Ubuntu"
    - name: install apache2 package and php packages for Ubuntu
      apt:
        name:
          - apache2
          - libapache2-mod-php
        state: latest
        when: ansible_distribution == "Ubuntu"
    - name: update repository index for centos
      dnf:
        update_cache: yes
        when: ansible_distribution == "Centos"
    - name: install apache2 package
      dnf:
        name:
          - httpd
          - php
        state: latest
        when: ansible_distribution == "Centos"
```

Run *ansible-playbook --ask-become-pass install\_apache.yml* and describe the result.

```

rustom@localmachine:~/CPE232_RUSTOM$ ansible-playbook --ask-become-pass install_apache.yml
BECOME password:

PLAY [all] *****

TASK [Gathering Facts] *****
ok: [192.168.56.108]
ok: [192.168.56.109]
ok: [192.168.56.118]

TASK [update repository index for ubuntu] *****
skipping: [192.168.56.118]
changed: [192.168.56.108]
changed: [192.168.56.109]

TASK [install apache2 package and php packages for ubuntu] *****
skipping: [192.168.56.118]

192.168.56.108      : ok=3    changed=1    unreachable=0    failed=0    skipped=2    rescued=0    ignor
192.168.56.109      : ok=3    changed=1    unreachable=0    failed=0    skipped=2    rescued=0    ignor
192.168.56.118      : ok=1    changed=0    unreachable=0    failed=0    skipped=4    rescued=0    ignor

```

2. Edit the playbook *install\_apache.yml* again. In task 2.1, we consolidated the plays into one play. This time we can actually consolidated everything in just 2 plays. This can be done by removing the update repository play and putting the command *update\_cache: yes* below the command *state: latest*. See below for reference:

```

---
- hosts: all
  become: true
  tasks:

    - name: install apache2 and php packages for Ubuntu
      apt:
        name:
          - apache2
          - libapache2-mod-php
        state: latest
        update_cache: yes
      when: ansible_distribution == "Ubuntu"

    - name: install apache and php packages for CentOS
      dnf:
        name:
          - httpd
          - php
        state: latest
        update_cache: yes
      when: ansible_distribution == "CentOS"

```

Make sure to save the file and exit.

```

GNU nano 6.2                                install_apache.yml
--
- hosts: all
  become: true
  tasks:

    - name: install apache2 package and php packages for Ubuntu
      apt:
        name:
          - apache2
          - libapache2-mod-php
        state: latest
        update_cache: yes
        when: ansible_distribution == "Ubuntu"

    - name: install apache and php package for Centos
      dnf:
        name:
          - httpd
          - php
        state: latest
        update_cache: yes
        when: ansible_distribution == "Centos"

```

Run *ansible-playbook --ask-become-pass install\_apache.yml* and describe the result.

```

rustom@localmachine:~/CPE232_RUSTOM$ ansible-playbook --ask-become-pass install_apache.yml
BECOME password:

PLAY [all] *****

192.168.56.109      : ok=2    changed=0    unreachable=0    failed=0    skipped=1    rescued=0
192.168.56.118      : ok=1    changed=0    unreachable=0    failed=0    skipped=2    rescued=0

```

- Finally, we can consolidate these 2 plays in just 1 play. This can be done by declaring variables that will represent the packages that we want to install. Basically, the `apache_package` and `php_package` are variables. The names are arbitrary, which means we can choose different names. We also take out

the line when: ansible\_distribution. Edit the playbook *install\_apache.yml* again and make sure to follow the below image. Make sure to save the file and exit.

```
---
- hosts: all
  become: true
  tasks:

    - name: install apache and php
      apt:
        name:
          - "{{ apache_package }}"
          - "{{ php_package }}"
        state: latest
        update_cache: yes
```

```
GNU nano 6.2 install_apache.yml
---
- hosts: all
  become: true
  tasks:

    - name: install apache2 package and php
      apt:
        name:
          - "{{ apache_package }}"
          - "{{ php_package }}"
        state: latest
        update_cache: yes"
```

Run *ansible-playbook --ask-become-pass install\_apache.yml* and describe the result.

```

rustom@localmachine:~/CPE232_RUSTOM$ ansible-playbook --ask-become-pass install_apache.yml
BECOME password:

PLAY [all] *****

TASK [Gathering Facts] *****
ok: [192.168.56.109]
ok: [192.168.56.108]

PLAY RECAP *****
192.168.56.108      : ok=1    changed=0    unreachable=0    failed=1    skipped=0    rescued=0
192.168.56.109      : ok=1    changed=0    unreachable=0    failed=1    skipped=0    rescued=0
192.168.56.118      : ok=1    changed=0    unreachable=0    failed=1    skipped=0    rescued=0

```

4. Unfortunately, task 2.3 was not successful. It's because we need to change something in the inventory file so that the variables we declared will be in place. Edit the *inventory* file and follow the below configuration:

```

192.168.56.120 apache_package=apache2 php_package=libapache2-mod-php
192.168.56.121 apache_package=apache2 php_package=libapache2-mod-php
192.168.56.122 apache_package=httpd php_package=php

```

Make sure to save the *inventory* file and exit.

**Finally**, we still have one more thing to change in our *install\_apache.yml* file. In task 2.3, you may notice that the package is assign as *apt*, which will not run in CentOS. Replace the *apt* with *package*. Package is a module in ansible that is generic, which is going to use whatever package manager the underlying host or the target server uses. For Ubuntu it will automatically use *apt*, and for CentOS it will automatically use *dnf*. Make sure to save the file and exit. For more details about the ansible package, you may refer to this documentation: [ansible.builtin.package – Generic OS package manager — Ansible Documentation](#)

Run *ansible-playbook --ask-become-pass install\_apache.yml* and describe the result.

```

rustom@localmachine:~/CPE232_RUSTOM$ ansible-playbook --ask-become-pass install_apache.yml
BECOME password:

PLAY [all] *****

TASK [Gathering Facts] *****
ok: [192.168.56.109]
ok: [192.168.56.108]
ok: [192.168.56.118]

TASK [install apache2 and php] *****
ok: [192.168.56.109]
ok: [192.168.56.118]
ok: [192.168.56.108]

PLAY RECAP *****
192.168.56.108      : ok=2    changed=0    unreachable=0    failed=0    skipped=0    rescued=0    ignor
192.168.56.109      : ok=2    changed=0    unreachable=0    failed=0    skipped=0    rescued=0    ignor
192.168.56.118      : ok=2    changed=0    unreachable=0    failed=0    skipped=0    rescued=0    ignor

```

- After replacing the apt with the package in install\_apache.yml and modifying the inventory, the playbook was executed without a problem.

## Reflections:

Answer the following:

### 1. Why do you think refactoring of playbook codes is important?

- Refactoring of playbooks is important in terms of efficiency since you can shorten your playbook codes but same function and it can be easier to debug because you can analyze or scan the playbook code looking for the mistake since there are few lines and columns. For example, an efficient way of refactoring the playbook is using a package instead of having two different modules which are apt for Ubuntu and dnf for centos.

### 2. When do we use the “when” command in the playbook?

- “when” is used in the playbook when there is a conditional statement. Basically the “when” command is executed in a specific task or goals depending on the condition in your when command. “when” command is useful because you can control the execution of the task within the playbook depends on the condition .In this activity the “when” command is commonly used to execute commands in a specific linux distribution which is the centos and ubuntu.
